11 **Abstract**

12 We present a new approach for the outflow boundary conditions of Navier-
13 Stokes equations in hemodynamics. We first describe some existing 3D-0D cou-
14 pling methods and highlight benefits and disadvantages of each of them. We then
15 introduce a new method that consists in adding a 3D artificial part where the
16 Navier-Stokes equations are modified to obtain an equivalent energy balance to
17 a standard coupling with a 3-element Windkessel model. We investigate theoret-
18 ically the stability of the system and compare it to previously introduced methods.
19 Finally we compare these coupling methods for numerical simulations of blood
20 flow in three patient-specific models, which represent different flow regimes in
21 the pulmonary and systemic circulations. The new method, especially in its hybrid
22 form, is a possible alternative to existing methods. It can be in particular convenient
23 in codes that do not allow users to implement non-standard boundary conditions.

24 **1. Introduction**

25 The three-dimensional Navier-Stokes simulation of blood flow in large vessels re-
26 quires inlet and outlet boundary conditions that represent hemodynamics at these
27 locations. However, in patient-specific settings, pressure or velocity are rarely clin-
28 ically measured exactly there, or they can be part of the desired output [43]. Thus,
29 boundary conditions are usually substituted for transmission conditions with re-
30 duced models of the rest of the circulation. This typically involves coupling to 1D
31 models (e.g. [8, 15, 33, 41]), or simple lumped parameter 0D models (e.g. [18,
32 37, 42, 44]) or closed loop lumped parameter 0D models (e.g. [3, 10, 25, 28, 30]).
33 This coupling methodology transfers in various forms pressure and flow rate be-
34 tween 3D and reduced models, for which there is a loss of information. Moreover,
35 reverse flow may occur in parts of or on entire coupling boundaries. This calls for

36 careful coupling conditions, so that the scheme is stable, without altering too much
37 the local flow dynamics.

38

39 A first coupling method consists in enforcing a uniform pressure obtained from the
40 reduced model at the coupling boundary. When a variational formulation is used,
41 e.g. with the finite element method, it is more natural to replace the pressure with
42 the normal component of the normal stress. However stability analyses show that
43 the convective term on the boundary can be responsible for numerical instabilities
44 in the presence of reverse flow. Some Navier-Stokes formulations involve the total
45 pressure in their natural boundary conditions (e.g. [5]). This has been shown to
46 lead to an energetically stable coupling between 3D and reduced models of blood
47 flow (e.g. [16, 17]). Several authors have been expecting instabilities when the
48 total pressure is not included in the transmission conditions but have not seen them
49 numerically [9, 17]. In formulations based on static pressure, a dissipative stabi-
50 lization has been proposed to counteract the destabilizing effect of the convective
51 boundary term (see [4]). We also refer to [11, 12] where similar ideas were intro-
52 duced. A boundary condition based on enforcing the continuity of pressure on the
53 one hand and of a linear combination of flow and energy fluxes on the other hand,
54 has been proven to be energetically stable, but it does not necessarily conserve mass
55 [14]. More recently, a local regularization of the fluid velocity along the tangential
56 directions has been developed in [6]. In all these methods, the reduced model pres-
57 sure is imposed as a uniform boundary condition for the Navier-Stokes equations.
58 But in complex flow, such as with reverse flow, there is *a priori* no reason that the
59 normal traction or the total pressure is uniform on a coupling boundary. For sta-
60 bilized methods, the added term introduces some non-uniformity that has also no
61 obvious reason to correspond to the physiological flow at hand.

62

63 In this article, we propose a new method to handle the outflow boundary condi-
64 tions, by coupling the 3D Navier-Stokes equations with another 3D compartment.
65 This artificial compartment involves modified Navier-Stokes equations that mimic
66 a three-element Windkessel model [19] (as an example of reduced model). The
67 advantages of such an approach are that the coupling 1) does not enforce a uniform
68 traction at the interface, 2) is energetically close to the usual 3D Navier-Stokes
69 - Windkessel solution, without the potentially destabilizing convective boundary
70 term, 3) is provably stable in the energy norm without needing a total pressure for-
71 mulation. Besides, a strategy of adding an artificial 3D part can be very useful in
72 a commercial code that does not allow the users to implement any 0D boundary
73 conditions.

74 Our contributions with respect to the existing works considering a 3D com-
75 partment (e.g. [27]) are the following. First, our artificial compartment is more
76 complex since it includes two different kinds of dissipation and one term repre-
77 senting an elastic potential energy. This allows us to mimic an RCR Windkessel
78 model, which is important in our applications. Second, we investigate how this
79 artificial compartment affects outflow instabilities typically encountered in hemo-
80 dynamics; third, we make a numerical comparison of different outflow boundary
81 conditions in realistic hemodynamics test cases.

82

83 In the next part of this article we present existing coupling methods, derive the cor-
84 responding energy balance. In this context, we present our new modified Navier-
85 Stokes system and analyze its stability. The last part of the methods section is
86 devoted to the numerical implementation. The results are then illustrated on differ-
87 ent reverse flow situations, namely three patient-specific cases of numerical blood
88 flow simulations in arteries in the pulmonary and the systemic sides for healthy or
89 diseased configurations. The different methods are compared qualitatively, looking

at the velocity fields at the coupling interface, and quantitatively on the flow and pressure. In some cases, the results are compared to a reference solution obtained on a larger geometry. Finally, a discussion with results of the literature is proposed and possible extensions are presented.

2. Methods

2.1. Problem formulations

Blood is assumed to be a Newtonian fluid flowing in a rigid domain Ω_1 . The incompressible Navier-Stokes equations are solved with no-slip condition on the wall Γ and with a Dirichlet boundary condition on the velocity at the inlet Γ_{in} (the notation is defined in Figure 1):

$$\rho \frac{\partial \mathbf{u}}{\partial t} + \rho(\mathbf{u} \cdot \nabla \mathbf{u}) + \nabla p - 2\mu \nabla \cdot \boldsymbol{\varepsilon}(\mathbf{u}) = 0 \quad (1)$$

$$\nabla \cdot \mathbf{u} = 0 \quad (2)$$

$$\mathbf{u}|_{\Gamma} = 0 \quad (3)$$

$$\mathbf{u}|_{\Gamma_{\text{in}}} = \mathbf{u}_{\text{in}} \quad (4)$$

where $\mathbf{u} : \Omega_1 \times \mathbb{R}^+ \rightarrow \mathbb{R}^3$ is the velocity, $p : \Omega_1 \times \mathbb{R}^+ \rightarrow \mathbb{R}$ is the pressure, and $\boldsymbol{\varepsilon}(\mathbf{u}) = \frac{1}{2}(\nabla \mathbf{u} + \nabla \mathbf{u}^T)$ denotes the strain rate tensor.

The system (1)-(4) has to be complemented with boundary conditions at the outlet Γ_{out} , where the Navier-Stokes equations are coupled to a reduced-order model which takes into account the rest of the vessels. Here the names “inlet” and “outlet” are chosen for convenience, but any of these can have some positive or negative flow rate over time. Three possible approaches that have been proposed in the literature are presented below. Then, the main contribution of this study, based on a 3D-3D coupling, is introduced.

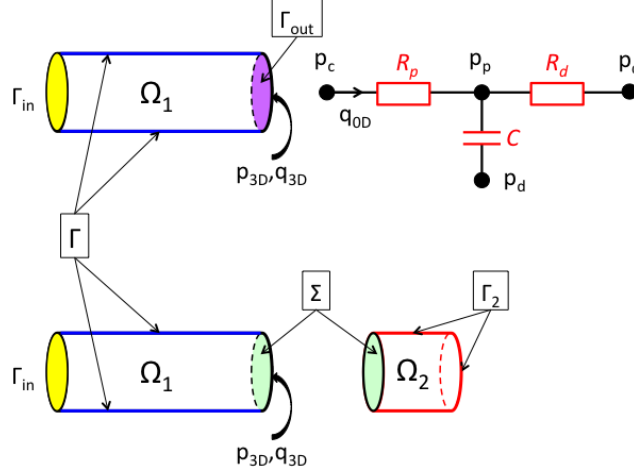

Figure 1: top: 3D-0D coupling scheme, bottom: 3D-3D coupling scheme.

2.2. Review of three existing approaches

Formulation 1: 3D-0D. The most common idea consists in enforcing a uniform normal stress at the outlet, equal to a pressure p_c given by a reduced model:

$$\boldsymbol{\sigma} \cdot \mathbf{n} = -p_c \mathbf{n}, \quad \text{on } \Gamma_{\text{out}}, \quad (5)$$

where $\boldsymbol{\sigma} = -p\mathbf{I} + 2\mu\boldsymbol{\varepsilon}(\mathbf{u})$. In a finite element framework, this is easily done with a Neumann boundary condition. The advantage of this formulation is its simplicity. Although stable in many practical situations, instabilities can be observed in presence of complex reverse flow. It will be shown in Section 2.4 that an uncontrolled term appears in the energy balance. This is a possible reason of the observed instabilities. In addition, enforcing a uniform normal stress on a section where the flow is complex may generate spurious vortices that can also lead to instabilities.

119 *Formulation 2: 3D-0D-Stab* . To cure the instabilities that may appear during
 120 backflow with Formulation 1, a stabilization method was proposed in [4]. This
 121 approach consists in modifying (5) as follows (here written in a slightly more gen-
 122 eral form):

$$\boldsymbol{\sigma} \cdot \mathbf{n} = -p_c \mathbf{n} - \rho \theta (\mathbf{u} \cdot \mathbf{n})_- \mathbf{u}, \quad \text{on } \Gamma_{\text{out}}, \quad (6)$$

123 where $(\mathbf{u} \cdot \mathbf{n})_-$ is equal to $-(\mathbf{u} \cdot \mathbf{n})$ if $\mathbf{u} \cdot \mathbf{n} \leq 0$, and is equal to 0 if not, and where θ
 124 has to be fixed.

125 This method is simple to implement and can be shown to be stable in the energy
 126 norm for $\theta \geq 0.5$. In practice, it proves to be very efficient at reducing the outlet
 127 instabilities. It was successfully tested in particular in [29, 36]. Two situations have
 128 to be distinguished here. When the backflow is due to spurious vortices induced by
 129 the presence of an artificial boundary, this effect is desirable. But it is well-known
 130 that a physical backflow can appear in some vessels during diastole. In those cases,
 131 the stabilization term artificially takes out of the system an energy that should enter
 132 through the outlet.

133 *Formulation 3: 3D-0D-Ptot* . Another approach considers a formulation of the
 134 Navier-Stokes equations that involves the total pressure (e.g. [5, 22]):

$$\boldsymbol{\sigma} \cdot \mathbf{n} - \frac{\rho}{2} |\mathbf{u}|^2 \mathbf{n} = -p_c \mathbf{n}, \quad \text{on } \Gamma_{\text{out}}. \quad (7)$$

135 This formulation, advocated in particular in [16, 17], can be proved to be stable in
 136 the energy norm (see below). But in blood flow, the total stress is far from being
 137 uniform on a section. Note that this is even not true for Poiseuille or Womersley
 138 flows. As a consequence, this formulation leads to large spurious velocity vectors,
 139 even for simple configurations [22]. As in Formulation 1, spurious vortices can be
 140 generated at this interface and can eventually trigger instabilities.

141 2.3. A new formulation

142 *Formulation 4a: 3D-3D* . We propose a possible alternative to the previous ap-
 143 proaches. System (1)-(4) is coupled to a modified Navier-Stokes system. Instead
 144 of a 0D model, an artificial 3D domain Ω_2 is added to the 3D domain of interest Ω_1
 145 (bottom of Figure 1). In Ω_2 , the Navier-Stokes equations are modified by adding
 146 terms to recover an energy balance similar to the one obtained with Formulation 3.
 147 The resulting system can be written in a compact form in $\Omega_1 \cup \Omega_2$:

$$\rho \frac{\partial \mathbf{u}}{\partial t} + \rho \mathbf{u} \cdot \nabla \mathbf{u} + \nabla p - 2\mu \nabla \cdot \boldsymbol{\varepsilon}(\mathbf{u}) + \gamma \mathbf{u} + \rho \frac{\mathbf{u}}{2} \nabla \cdot \mathbf{u} = 0 \quad (8)$$

$$\alpha \frac{\partial p}{\partial t} + \beta p + \nabla \cdot \mathbf{u} = 0 \quad (9)$$

$$\mathbf{u}|_{\Gamma_2} = 0 \quad (10)$$

148 where α, β and γ vanish in Ω_1 , to recover the standard equations (1)-(4), and are
 149 positive in Ω_2 . As indicated in Figure 1, the surface Γ_2 consists of the wall of
 150 the added artificial volume, i.e. $\Gamma_2 = \partial\Omega_2 \setminus \Sigma$. In other words the added artificial
 151 surface acts as a ‘‘cork’’.

152 Parameter α is a distributed version of the capacitance (C) in the Windkessel model.
 153 Parameters γ and $1/\beta$ play the role of the proximal (R_p) and distal (R_d) resistances
 154 respectively. Their values will be discussed in Section 2.4. Note that the term βp
 155 acts as a sink, whereas the term $\alpha \partial_t p$ acts as a sink when the pressure increases and
 156 as a source when the pressure decreases. The additional term $\rho \frac{\mathbf{u}}{2} \nabla \cdot \mathbf{u}$ is necessary to
 157 ensure stability in the energy norm, because the fluid is no longer incompressible in
 158 the artificial domain Ω_2 . The equations in the two domains Ω_1 and Ω_2 are coupled
 159 through the usual transmission conditions, with \mathbf{n} being defined on Σ as going from
 160 Ω_1 to Ω_2 :

$$\mathbf{u}_1 = \mathbf{u}_2, \text{ and } \boldsymbol{\sigma}_1 \cdot \mathbf{n} = \boldsymbol{\sigma}_2 \cdot \mathbf{n}, \quad \text{on } \Sigma, \quad (11)$$

161 which are automatically satisfied when a standard variational formulation of equa-
 162 tions (8)-(10) is set on the whole domain $\Omega_1 \cup \Omega_2$.

163 Contrary to what happened with the three previous formulations, the information
 164 coming from the “downstream part” is not uniform on the outflow section Γ_{out} .

165 Contrary to Formulation 1, an inequality can be proved to control the energy of the
 166 system. Compared to Formulation 2, it can let energy enter into the system through
 167 Γ_{out} in the presence of a physical backflow.

168 *Formulation 4b.* As a variant, we also propose a hybrid **3D-3D-0D** coupling method
 169 where the Navier-Stokes equations are coupled to the modified Navier-Stokes model,
 170 which is itself coupled to a 3-element Windkessel reduced model, as shown in Fig-
 171 ure 2 .

172

Figure 2: **3D-3D-0D** coupling approach (formulation 4b), where Ω_1 is the domain of interest, Ω_2 is an artificial added part, coupled to a 3-element Windkessel model.

173 In the whole domain $\Omega_1 \cup \Omega_2$,

$$\rho \frac{\partial \mathbf{u}}{\partial t} + \rho(\mathbf{u} \cdot \nabla \mathbf{u}) + \nabla p - 2\mu \nabla \cdot \boldsymbol{\varepsilon}(\mathbf{u}) + \gamma \mathbf{u} = 0 \quad (12)$$

$$\nabla \cdot \mathbf{u} = 0 \quad (13)$$

$$\mathbf{u}|_{\Gamma_1 \cup \Gamma_2} = 0 \quad (14)$$

$$\mathbf{u}|_{\Gamma_{\text{in}}} = \mathbf{u}_{\text{in}} \quad (15)$$

174 where $\gamma = 0$ in Ω_1 , with the usual transmission conditions (11). We finally couple
 175 a 3-element Windkessel model to the system (12)-(15) with the **3D-0D** coupling
 176 method,

$$\boldsymbol{\sigma} \cdot \mathbf{n} = -p_c \mathbf{n}, \quad \text{on } \Gamma_{\text{out}}, \quad (16)$$

177 2.4. Stability analysis

178 In this section, the energy equations of the various formulations presented above
 179 are derived. Without loss of generality, the reduced-order model providing the
 180 pressure p_c in Formulations 1, 2 and 3, is assumed for now to result from a standard
 181 RCR Windkessel model (Figure 1, top):

$$C \frac{dp_p}{dt} + \frac{p_p - p_d}{R_d} = q \quad (17)$$

$$p_c - p_p = R_p q \quad (18)$$

182 where $q = \int_{\Gamma_{\text{out}}} \mathbf{u} \cdot \mathbf{n} ds$. For the sake of simplicity, we assume that the distal pressure
 183 p_d is constant and equal to zero.

184

185 Multiplying (18) by q and (17) by p_p leads to the energy equation of the lumped
 186 parameter model:

$$p_c q = C \frac{d}{dt} \left(\frac{p_p^2}{2} \right) + R_p q^2 + \frac{p_p^2}{R_d} \quad (19)$$

We define the kinetic energy $E_{K_{\Omega_1}}$, the viscous power $P_{V_{\Omega_1}}$ and the energy P_{in} entering the domain through Γ_{in} , respectively by:

$$E_{K_{\Omega_1}} = \int_{\Omega_1} \frac{\rho}{2} |\mathbf{u}|^2 dx, \quad (20)$$

$$P_{V_{\Omega_1}} = 2\mu \int_{\Omega_1} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{\varepsilon}(\mathbf{u}) dx, \quad (21)$$

$$P_{\text{in}} = \int_{\Gamma_{\text{in}}} \boldsymbol{\sigma} \cdot \mathbf{n} \cdot \mathbf{u} ds - \rho \int_{\Gamma_{\text{in}}} \frac{|\mathbf{u}|^2}{2} \mathbf{n} \cdot \mathbf{u} ds. \quad (22)$$

187 *Energy balance of Formulation 1 (3D-0D coupling).* Multiplying (1) by \mathbf{u} and
188 integrating over Ω_1 :

$$\frac{d}{dt} \int_{\Omega_1} \frac{\rho}{2} |\mathbf{u}|^2 dx + \rho \int_{\Omega_1} \mathbf{u} \cdot \nabla \left(\frac{|\mathbf{u}|^2}{2} \right) dx + 2\mu \int_{\Omega_1} \boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{\varepsilon}(\mathbf{u}) dx + \int_{\Omega_1} \nabla p \cdot \mathbf{u} dx = 0. \quad (23)$$

189 Using (2) and the no-slip condition on the wall, the energy equation in Ω_1 reads:

$$\frac{d}{dt} E_{K_{\Omega_1}} + P_{V_{\Omega_1}} = P_{\text{in}} + \int_{\Gamma_{\text{out}}} \boldsymbol{\sigma} \cdot \mathbf{n} \cdot \mathbf{u} ds - \rho \int_{\Gamma_{\text{out}}} \frac{|\mathbf{u}|^2}{2} \mathbf{n} \cdot \mathbf{u} ds.$$

190 Considering the coupling condition (5) and the energy equation of the 0D model
191 (19), the global energy balance of the **3D-0D** coupling method is obtained:

$$\frac{d}{dt} E_{K_{\Omega_1}} + P_{V_{\Omega_1}} + C \frac{d}{dt} \frac{p_p^2}{2} + \frac{p_p^2}{R_d} + R_p q^2 = P_{\text{in}} - \rho \int_{\Gamma_{\text{out}}} \frac{|\mathbf{u}|^2}{2} \mathbf{n} \cdot \mathbf{u} ds \quad (24)$$

192 In the presence of reverse flow at an outlet ($\mathbf{u} \cdot \mathbf{n} < 0$) the last term may thus have
193 a destabilizing effect.

194 *Energy balance of Formulation 2 (3D-0D-Stab coupling).* With the same compu-
195 tation as in Formulation 1, but considering (6) instead of (5) as a coupling condi-
196 tion, the energy equation of Formulation 2 reads:

$$\frac{d}{dt} E_{K_{\Omega_1}} + P_{V_{\Omega_1}} + C \frac{d}{dt} \frac{p_p^2}{2} + \frac{p_p^2}{R_d} + R_p q^2 = \begin{cases} P_{\text{in}} - \frac{\rho}{2} \int_{\Gamma_{\text{out}}} |\mathbf{u}|^2 (\mathbf{u} \cdot \mathbf{n}) ds, & \text{if } \mathbf{u} \cdot \mathbf{n} \geq 0 \\ P_{\text{in}} - \rho(\frac{1}{2} - \theta) \int_{\Gamma_{\text{out}}} |\mathbf{u}|^2 (\mathbf{u} \cdot \mathbf{n}) ds, & \text{if } \mathbf{u} \cdot \mathbf{n} < 0 \end{cases} \quad (25)$$

197 This formulation is therefore stable in the energy norm for $\theta \geq 0.5$. If $\theta = 0.5$,
 198 as in [29, 36], the potentially destabilizing term of (24) is exactly balanced by the
 199 artificial dissipation when $\mathbf{u} \cdot \mathbf{n} < 0$. In some publications, a stronger dissipation is
 200 chosen (e.g. $\theta = 1$ in [4]).

201 *Energy balance of Formulation 3 (3D-0D-Ptot coupling):* . When coupling is done
 202 with the total pressure (7), the potentially destabilizing term of (24) disappears in
 203 the energy balance:

$$\frac{d}{dt}E_{K_{\Omega_1}} + P_{V_{\Omega_1}} + C \frac{d}{dt} \frac{p_p^2}{2} + \frac{p_p^2}{R_d} + R_p \mathbf{q}^2 = P_{\text{in}} \quad (26)$$

204 This formulation is therefore stable in the energy norm.

205 *Energy balance of Formulation 4a (3D-3D coupling):*. As in Formulation 1, the
 206 energy equation in the domain of interest Ω_1 reads:

$$\frac{d}{dt}E_{K_{\Omega_1}} + P_{V_{\Omega_1}} = P_{\text{in}}^{\Omega_1} + \int_{\Sigma} (\boldsymbol{\sigma} \cdot \mathbf{n} \cdot \mathbf{u} - \rho \frac{|\mathbf{u}|^2}{2} \mathbf{n} \cdot \mathbf{u}) ds \quad (27)$$

207 Similarly, in the artificial domain Ω_2 , from the modified Navier-Stokes equation
 208 (8)-(9)-(10):

$$\frac{d}{dt}E_{K_{\Omega_2}} + P_{V_{\Omega_2}} + \gamma \int_{\Omega_2} |\mathbf{u}|^2 dx - \int_{\Omega_2} p \nabla \cdot \mathbf{u} dx = - \int_{\Sigma} \boldsymbol{\sigma} \cdot \mathbf{n} \cdot \mathbf{u} ds + \rho \int_{\Sigma} \frac{|\mathbf{u}|^2}{2} \mathbf{n} \cdot \mathbf{u} ds \quad (28)$$

209 Using equation (9),

$$\begin{aligned} & \frac{d}{dt}E_{K_{\Omega_2}} + P_{V_{\Omega_2}} + \alpha \frac{d}{dt} \int_{\Omega_2} \frac{p^2}{2} dx + \beta \int_{\Omega_2} p^2 dx + \gamma \int_{\Omega_2} |\mathbf{u}|^2 dx \\ & = - \int_{\Sigma} \boldsymbol{\sigma} \cdot \mathbf{n} \cdot \mathbf{u} ds + \rho \int_{\Sigma} \frac{|\mathbf{u}|^2}{2} \mathbf{n} \cdot \mathbf{u} ds \end{aligned} \quad (29)$$

210 Adding these two relations, the boundary terms in the right-hand side cancel out,
 211 due to the transmission condition (11), and the energy balance of Formulation 4a
 212 is obtained:

$$\frac{d}{dt}E_K^{\Omega_1 \cup \Omega_2} + P_V^{\Omega_1 \cup \Omega_2} + \alpha \frac{d}{dt} \int_{\Omega_2} \frac{p^2}{2} dx + \beta \int_{\Omega_2} p^2 dx + \gamma \int_{\Omega_2} |\mathbf{u}|^2 dx = P_{\text{in}}^{\Omega_1}. \quad (30)$$

213 This formulation is therefore stable in the energy norm. Comparing (30) with (26),
 214 we notice an analogy between α, β, γ and the standard Winkessel parameters. From
 215 this observation, we can set:

$$\alpha \approx C/V, \beta \approx 1/(R_d V), \gamma \approx R_p S/L, \quad (31)$$

216 where V, S and L respectively denote the volume, the section and the length of the
 217 artificial domain Ω_2 .

218 Similarly, the energy balance of *Formulation 4b* (**3D-3D-0D** coupling) is thus:

$$\begin{aligned} & \frac{d}{dt} E_K^{\Omega_1 \cup \Omega_2} + P_V^{\Omega_1 \cup \Omega_2} + \gamma \int_{\Omega_2} |\mathbf{u}|^2 dx \\ & + C \frac{d}{dt} \frac{p_p^2}{2} + \frac{p_p^2}{R_d} + R_p q^2 = P_{\text{in}}^{\Omega_1} - \rho \int_{\Gamma_{\text{out}}} \frac{|\mathbf{u}|^2}{2} \mathbf{n} \cdot \mathbf{u} ds. \end{aligned} \quad (32)$$

219 In this hybrid formulation, the outlet inertial term reappears, but, as will be seen in
 220 the results, this formulation is stable in practice.

221 2.5. Numerical schemes

222 The RCR Windkessel model is discretized with a first-order scheme: assuming that
 223 p_p^n and q^n are known, then p_p^{n+1} and p_c^{n+1} are defined by

$$\begin{aligned} C \frac{p_p^{n+1} - p_p^n}{\Delta t} + \frac{p_p^{n+1}}{R_d} &= q^n, \\ p_c^{n+1} &= p_p^{n+1} + R_p q^n. \end{aligned} \quad (33)$$

224 Denoting $R_d C$ by τ , the pressure transmitted to the 3D model at time t^{n+1} is given
 225 by:

$$p_c^{n+1} = \frac{\frac{\tau}{\Delta t} p_p^n + R_d q^n}{1 + \frac{\tau}{\Delta t}} + R_p q^n. \quad (34)$$

226 The 3D formulations are discretized with a first-order time scheme and P1/P1 sta-
 227 bilized finite element [35]. The nonlinear advection term of the Navier-Stokes

equations is treated semi-implicitly. In the following the finite element test functions for the momentum and continuity equations are respectively denoted by \mathbf{v}_h and q_h .

Formulation 1 (3D-0D). Defining the bilinear form:

$$\begin{aligned} A_1^\Omega(\mathbf{u}_h^n; (\mathbf{u}_h^{n+1}, p_h^{n+1}), (\mathbf{v}_h, q_h)) &= \int_\Omega \left(\frac{\rho}{\Delta t} \mathbf{u}_h^{n+1} + \rho \mathbf{u}_h^n \cdot \nabla \mathbf{u}_h^{n+1} \right) \cdot \mathbf{v}_h dx \\ &+ \int_\Omega \mu \nabla \mathbf{u}_h^{n+1} : \nabla \mathbf{v}_h dx - \int_\Omega \left(p_h^{n+1} \nabla \cdot \mathbf{v}_h + q_h \nabla \cdot \mathbf{u}_h^{n+1} \right) dx, \end{aligned} \quad (35)$$

the variational formulation of the **3D-0D** method reads: Find \mathbf{u}_h^{n+1} and p_h^{n+1} such that for every \mathbf{v}_h and q_h ,

$$A_1^{\Omega_1}(\mathbf{u}_h^n; (\mathbf{u}_h^{n+1}, p_h^{n+1}), (\mathbf{v}_h, q_h)) = \int_{\Omega_1} \frac{\rho}{\Delta t} \mathbf{u}_h^n \cdot \mathbf{v}_h dx - \int_{\Gamma_{\text{out}}} p_c^{n+1} \mathbf{n} \cdot \mathbf{v}_h ds \quad (36)$$

Remark 2.1. Note that the weak form of the viscous term is based on the relation $\mu \Delta \mathbf{u} = 2\mu \nabla \cdot \boldsymbol{\varepsilon}(\mathbf{u})$, valid for an incompressible fluid. The natural condition corresponding to this formulation is compatible with Poiseuille and Womersley flows contrary to the one based on $\boldsymbol{\varepsilon}(\mathbf{u})$ (e.g. [22]). We made this choice to avoid perturbations of the velocity field at the outlet for these basic flows, but the formulation based on $\boldsymbol{\varepsilon}(\mathbf{u})$ can also be used in practice.

Formulation 2 (3D-0D-Stab). Considering the bilinear form (35) and boundary conditions (6) with $\theta = 0.5$, the **3D-0D-Stab** method variational formulation reads:

Find \mathbf{u}_h^{n+1} and p_h^{n+1} such that for every \mathbf{v}_h and q_h ,

$$\begin{aligned} A_1^{\Omega_1}(\mathbf{u}_h^n; (\mathbf{u}_h^{n+1}, p_h^{n+1}), (\mathbf{v}_h, q_h)) &= \\ \int_{\Omega_1} \frac{\rho}{\Delta t} \mathbf{u}_h^n \cdot \mathbf{v}_h dx - \int_{\Gamma_{\text{out}}} p_c^{n+1} \mathbf{n} \cdot \mathbf{v}_h ds - \int_{\Gamma_{\text{out}}} \frac{\rho}{2} (\mathbf{u}_h^n \cdot \mathbf{n})_-(\mathbf{u}_h^{n+1} \cdot \mathbf{v}_h) ds \end{aligned} \quad (37)$$

Formulation 3 (3D-0D-Ptot). Defining the bilinear form:

$$\begin{aligned} A_2^\Omega(\mathbf{u}_h^n; (\mathbf{u}_h^{n+1}, p_h^{n+1}), (\mathbf{v}_h, q_h)) &= \int_\Omega \left(\frac{\rho}{\Delta t} \mathbf{u}_h^{n+1} + \rho (\nabla \times \mathbf{u}_h^{n+1}) \times \mathbf{u}_h^n \right) \cdot \mathbf{v}_h dx \\ &- \int_\Omega \frac{\rho}{2} \mathbf{u}_h^{n+1} \cdot \mathbf{u}_h^n \nabla \cdot \mathbf{v}_h dx + \int_{\Omega_1} \mu \nabla \mathbf{u}_h^{n+1} : \nabla \mathbf{v}_h dx - \int_\Omega \left(p_h^{n+1} \nabla \cdot \mathbf{v}_h + q_h \nabla \cdot \mathbf{u}_h^{n+1} \right) dx. \end{aligned} \quad (38)$$

244 The variational formulation of the **3D-0D-Ptot** method reads: Find \mathbf{u}_h^{n+1} and p_h^{n+1}
 245 such that for every \mathbf{v}_h and q_h ,

$$A_2^{\Omega_1}(\mathbf{u}_h^n; (\mathbf{u}_h^{n+1}, p_h^{n+1}), (\mathbf{v}_h, q_h)) = \int_{\Omega_1} \frac{\rho}{\Delta t} \mathbf{u}_h^n \cdot \mathbf{v}_h dx - \int_{\Gamma_{\text{out}}} p_c^{n+1} \mathbf{n} \cdot \mathbf{v}_h ds \quad (39)$$

246 **Remark 2.2.** *In this formulation, the total pressure only appears in the boundary*
 247 *condition but the pressure unknown is still the static pressure. It is also possible*
 248 *to consider a formulation, based on the relation $\mathbf{u} \cdot \nabla \mathbf{u}^T = \nabla \left(\frac{|\mathbf{u}|^2}{2} \right)$, where the static*
 249 *pressure is replaced by the total pressure as an unknown [22].*

250 *Formulation 4a (3D-3D).* Defining the bilinear form:

$$\begin{aligned} A_3^{\Omega}(\mathbf{u}_h^n; (\mathbf{u}_h^{n+1}, p_h^{n+1}), (\mathbf{v}_h, q_h)) &= \int_{\Omega} \left(\frac{\rho}{\Delta t} \mathbf{u}_h^{n+1} + \rho \mathbf{u}_h^n \cdot \nabla \mathbf{u}_h^{n+1} \right) \cdot \mathbf{v}_h dx \\ &\quad + \int_{\Omega} \mu \nabla \mathbf{u}_h^{n+1} : \nabla \mathbf{v}_h dx - \int_{\Omega} \left(p_h^{n+1} \nabla \cdot \mathbf{v}_h + q_h \nabla \cdot \mathbf{u}_h^{n+1} \right) dx \\ &\quad + \int_{\Omega} \gamma \mathbf{u}_h^{n+1} \cdot \mathbf{v}_h dx + \int_{\Omega} \frac{\rho}{2} \mathbf{u}_h^{n+1} \cdot \mathbf{v}_h \nabla \cdot \mathbf{u}_h^n dx - \int_{\Omega} \left(\frac{\alpha}{\Delta t} + \beta \right) p_h^{n+1} q_h dx \end{aligned} \quad (40)$$

251 where, $\alpha = \beta = \gamma = 0$ in Ω_1 .

252 The variational formulation of the **3D-3D** method reads: Find \mathbf{u}_h^{n+1} and p_h^{n+1} such
 253 that for every \mathbf{v}_h and q_h ,

$$A_3^{\Omega_1 \cup \Omega_2}(\mathbf{u}_h^n; (\mathbf{u}_h^{n+1}, p_h^{n+1}), (\mathbf{v}_h, q_h)) = \int_{\Omega_1 \cup \Omega_2} \left(\frac{\rho}{\Delta t} \mathbf{u}_h^n \cdot \mathbf{v}_h - \frac{\alpha}{\Delta t} p_h^n q_h \right) dx \quad (41)$$

254 The variational formulation of *Formulation 4b (3D-3D-0D)* is the same with the
 255 addition on the right hand side of $-\int_{\Gamma_{\text{out}}} p_c^{n+1} \mathbf{n} \cdot \mathbf{v}_h dx$, and taking $\alpha = 0, \beta = 0$.

256 3. Results

257 In this section we present results of all these coupling methods for patient-specific
 258 cases in the systemic and the pulmonary sides where the flow regimes are very
 259 different. The first case is a typical case of flow in pulmonary arteries: the flow

field is not so complex, and yet prescribed inlet back flow generates stability issues. For the second case the main advantages are first that the effect of artificially cutting the geometry can be assessed, and second that, due to the bifurcation close to the inlet, it is a case of more complex flow, although at the inlet no back flow is imposed. Finally, the third case tests a typical systemic hemodynamics scenario: instabilities there are generally observed during deceleration after peak systole. These three cases thus reflect the diversity of typical numerical instabilities seen in cardiovascular simulations. Through them, we highlight differences, benefits and disadvantages in the instability treatments.

For each case, the choice of Windkessel parameters is described. For the **3D-3D** model, parameters were chosen following equations 31, given the specific added volume dimensions. Finally, parameters of the hybrid **3D-3D-0D** method were defined as follows: in the artificial parts, γ is chosen as 10% of the γ in the **3D-3D** model, while correspondingly the proximal resistance of the Windkessel model is decreased by 10% compared to the original value.

3.1. Adult patient-specific pulmonary artery: a case with inlet backflow

This patient specific geometrical model is an adult pulmonary artery (PA). Velocity is prescribed at the inlet of the model, as a plug profile following the flow tracing of Figure 3. There is around 16% of reverse flow. The maximum flow rate is around $378\text{cm}^3/\text{s}$, leading to a highest Reynolds number of 2400. During the deceleration after systole, physical reverse flow occurs with a minimal flow rate around $-66\text{cm}^3/\text{s}$. Figure 3 also shows on the left-hand side the original geometrical model containing 107K tetrahedra, with both outlets coupled to 3-element Windkessel models by successively the **3D-0D**, **3D-0D-Stab** and **3D-0D-Ptot** methods.

286 On the right-hand side, the geometrical model with the added artificial parts con-
 287 sists of 127K tetrahedra: there the coupling is done with the **3D-3D** and **3D-3D-0D**
 288 methods.

289

Figure 3: Original geometrical model in blue (left) and geometrical model with the added outlet 3D artificial parts in red and purple (right). Inlet flow tracing over two cardiac cycles.

290 Table 1 summarizes the parameters of the different coupling methods. On the left-
 291 hand side, the Windkessel model parameters are the ones of the **3D-0D**, **3D-0D-**
 292 **Stab** and **3D-0D-Ptot** coupling approaches. They were chosen to represent physio-
 293 logical PA pressure pulses, assuming symmetry between the two lung vasculatures
 294 [21]. The **3D-3D** (right) and **3D-3D-0D** (below) parameters in the artificial added
 295 parts are displayed, given that the added volumes are such that V , S and L are re-
 296 spectively 5 cm^3 , 2.5 cm^2 , and 2 cm on both sides.

	LPA	RPA		Lc	Rc
R_p	$4 \cdot 10^1$	$4 \cdot 10^1$	γ	$4.9 \cdot 10^1$	$4.9 \cdot 10^1$
C	$1 \cdot 10^{-3}$	$1 \cdot 10^{-3}$	α	$2 \cdot 10^{-4}$	$2 \cdot 10^{-4}$
R_d	$3 \cdot 10^2$	$3 \cdot 10^2$	β	$6.7 \cdot 10^{-4}$	$6.7 \cdot 10^{-4}$

	Lout	Rout		Lc	Rc
R_p	$3.6 \cdot 10^1$	$3.6 \cdot 10^1$	γ	4.9	4.9
C	$1 \cdot 10^{-3}$	$1 \cdot 10^{-3}$	α	0	0
R_d	$3 \cdot 10^2$	$3 \cdot 10^2$	β	0	0

Table 1: R_p and R_d in $\text{g cm}^{-4} \text{s}^{-1}$, and C in $\text{g}^{-1} \text{cm}^4 \text{s}^2$, α in $\text{g}^{-1} \text{cm s}^2$, β in $\text{g}^{-1} \text{cm s}$, and γ in $\text{g cm}^{-3} \text{s}^{-1}$.

298 This example is a typical PA physiological case. In Figure 4 velocity fields are
 299 shown during forward peak flow (top) and in presence of backflow (bottom), com-
 300 paring the **3D-0D**, **3D-0D-Stab**, **3D-3D** and **3D-3D-0D** coupling methods. During
 301 forward flow, the four approaches lead to very similar velocity fields. In fact, in
 302 this configuration the convective stabilization is off, which is verified by the same
 303 results obtained for the **3D-0D** or **3D-0D-Stab** methods. During backflow, the
 304 **3D-0D** coupling method exhibits perturbations with inward vectors which are very
 305 large relative to the flow rate for a few time steps. The **3D-0D-Stab** method, while
 306 stable, perturbs the hemodynamics by reducing the velocity vectors to almost zero.
 307 The **3D-3D** approach allows to recover a backflow without instabilities, and simi-
 308 larly for **3D-3D-0D**.

309 In Figure 5, the **3D-0D-Ptot** method exhibits velocity vectors with strong spu-
 310 rious radial components at the outlet surface [22]. Spurious in and out of plane
 311 vectors can also be seen, even though flow is maximally forward. Moreover,
 312 computations are not diverging but lead to a very large in-plane pressure gradi-
 313 ent ($\Delta P = 26.50 \text{ mmHg}$), which is not relevant from a physiological point of view.

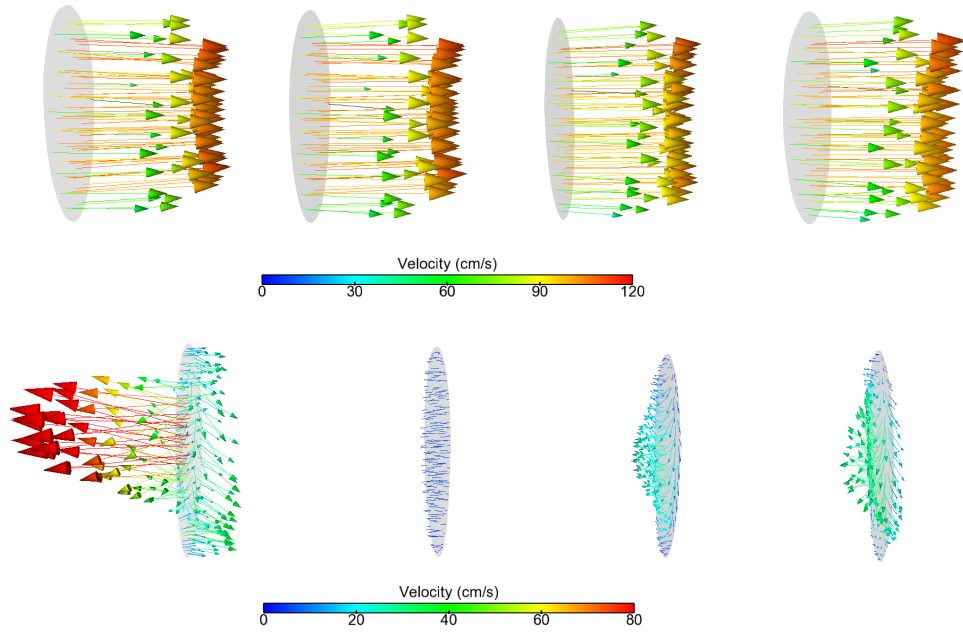

Figure 4: Velocity fields at the LPA interface, when flow at the inlet is maximal forward (top, $t=0.10s$, $Q_{\max} = 378 \text{ cm}^3/s$) and is reverse (bottom, $t=1.06s$, $Q_{\min} = -66 \text{ cm}^3/s$) with the **3D-0D**, **3D-0D-Stab**, **3D-3D** and **3D-3D-0D** coupling methods from left to right.

Figure 5: In-plane pressure relative to its minimum value (left) and velocity fields (right) at the LPA interface during maximal forward flow ($t=0.1s$) with the **3D-0D-Ptot** coupling method.

315 The time-varying flow rates and average pressure at the coupling surfaces are now
316 analyzed (Figure 6 shows the LPA). For each coupling method, similar flow and
317 pressure results are found on both the left and right-hand sides. Flow and pressure
318 from the **3D-0D-Ptot** method are not represented as the obtained values were non-
319 physiological: although the simulation did not diverge, they were too high with
320 spurious high-frequency tracings. For all other coupling methods, flow varies over
321 time very similarly. Pressure varies over 3 to 20 mmHg, in exactly the same way
322 for the **3D-0D** and **3D-0D-Stab** methods, but a few mmHg lower for the **3D-3D**
323 model, while for the **3D-3D-0D** model it is closer to the other couplings.

324 At this point however, it is hard to conclude on which method is best reproduc-
325 ing the real flow behavior, because we do not have access to the three dimensional
326 downstream domain. But this case is highlighting the robustness of the **3D-0D-**
327 **Stab** and **3D-3D** coupling methods to avoid large numerical artefacts due to phys-
328 iological reverse flow in a patient-specific case.

329

330 3.2. *Diseased child pulmonary arteries: a challenging fluid dynamics case*

331 This patient specific geometry is the first generation of a pulmonary arterial tree of
332 a child affected by a congenital heart disease, the single ventricle pathology (pul-
333 monary atresia with intact ventricular septum). This patient underwent a so-called
334 stage 1 surgical procedure consisting of an anastomosis between the systemic and
335 pulmonary circulatory systems *via* a 3.5mm artificial shunt. For more information
336 about this patient and its model reconstruction see [1].

337

338 Figure 7 represents the complete geometrical model (918K tetrahedra, six outlets),
339 the short model with cut pulmonary artery branches (471K tetrahedra, two outlets),
340 and the short model with its artificial parts to the outlet surfaces (505K tetrahedra,

Flow at left pulmonary artery

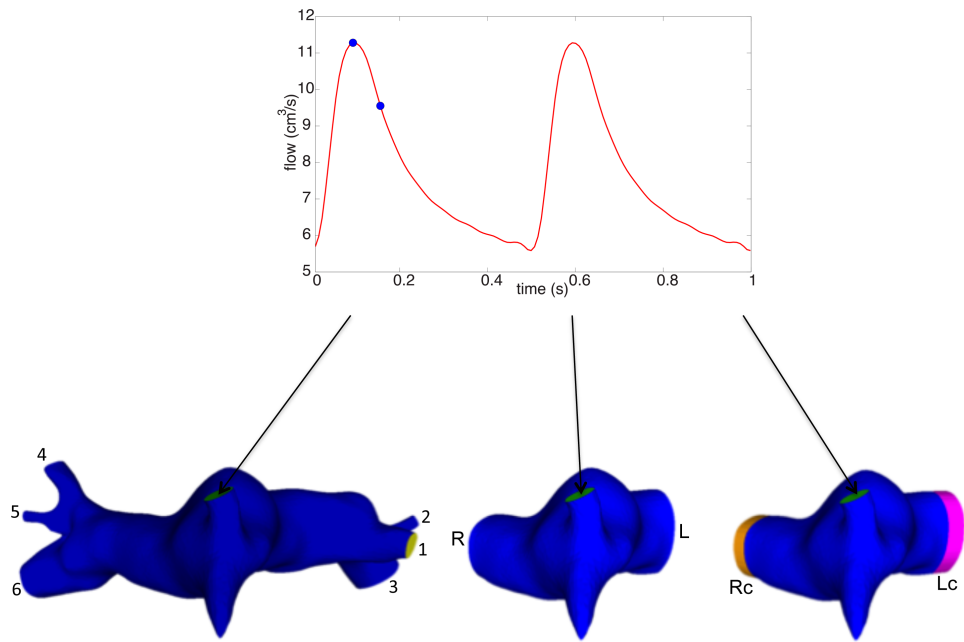

Figure 7: From left to right: complete model (with outlets 1 – 6), short model (two outlets, R for the RPA and L for the LPA), and short model with the two artificial three dimensional parts on each side, R_c and L_c . Top: imposed inflow shown over two cycles, with the two dots representing maximum flow and decelerating flow respectively.

2 outlets). As in the previous case, velocity was prescribed at the inlet with a plug profile, following a typical shunt flow tracing. The highest Reynolds number is 3000. The flow rate varies over one cardiac cycle between $5.8\text{cm}^3/\text{s}$ and $11.2\text{cm}^3/\text{s}$; there is thus no physical flow reversal prescribed at the inlet. The main advantages of this case are first that the effect of artificially cutting the geometry can be assessed, and second that, due to the bifurcation close to the inlet, it is a case of more complex flow than previously.

In Table 2 the values of proximal and distal resistances, and capacitances are given for each of the six outlets of the complete geometrical model. These values were generated to reflect clinical measurements [1, 2]. A first simulation is run with the **3D-0D** coupling approach on the complete geometry. All the coupling methods with the short models are then compared to this reference simulation.

353

	1	2	3		4	5	6
R_p	$3.19 \cdot 10^1$	$4.73 \cdot 10^1$	$6.38 \cdot 10^0$	R_p	$1.71 \cdot 10^1$	$4.26 \cdot 10^1$	$5.75 \cdot 10^0$
C	$4.40 \cdot 10^{-4}$	$1.79 \cdot 10^{-4}$	$5.50 \cdot 10^{-3}$	C	$1.14 \cdot 10^{-3}$	$2.35 \cdot 10^{-4}$	$1.06 \cdot 10^{-2}$
R_d	$2.45 \cdot 10^2$	$6.13 \cdot 10^2$	$2.95 \cdot 10^1$	R_d	$1.11 \cdot 10^2$	$4.63 \cdot 10^2$	$1.58 \cdot 10^1$

Table 2: R_p and R_d in $\text{g cm}^{-4} \text{s}^{-1}$, and C in $\text{g}^{-1} \text{cm}^4 \text{s}^2$ for the six Windkessel model outlets of the reference simulation in the complete geometrical model.

In Table 3, the reduced model parameters for the short geometries are given. They were generated from the reference model parameters: at both outlets, an equivalent impedance is computed from the three distal outlet Windkessel model of the complete model. Windkessel model parameters are then optimized to match this impedance. This Windkessel model is then coupled to the 3D Navier-Stokes equations with the **3D-0D**, **3D-0D-Stab** and **3D-0D-Ptot** methods. The **3D-3D** parameters in the artificial added parts are displayed, given that the added volumes are such that V , S and L are respectively 0.066 cm^3 , 0.33 cm^2 , and 0.2 cm for the left

side and 0.1 cm^3 , 0.49 cm^2 , and 0.2 cm for the right side, reflecting the smaller dimensions of this child anatomy. The **3D-3D-0D** parameters are hybrid between the **3D-0D** and **3D-3D** as described in the beginning of the section.

	R	L		Rc	Lc
R_p	$4.44 \cdot 10^0$	$5.28 \cdot 10^0$	γ	$7.13 \cdot 10^0$	$1.29 \cdot 10^1$
C	$1.29 \cdot 10^{-2}$	$6.20 \cdot 10^{-3}$	α	$1.96 \cdot 10^{-1}$	$6.35 \cdot 10^{-2}$
R_d	$1.33 \cdot 10^1$	$2.51 \cdot 10^1$	β	$1.14 \cdot 10^0$	$4.09 \cdot 10^{-1}$

Table 3: Parameters for the different coupling methods in the short models: R_p and R_d in $\text{g cm}^{-4} \text{ s}^{-1}$, and C in $\text{g}^{-1} \text{ cm}^4 \text{ s}^2$, α in $\text{g}^{-1} \text{ cm s}^2$, β in $\text{g}^{-1} \text{ cm s}$, and γ in $\text{g cm}^{-3} \text{ s}^{-1}$.

In Figure 8 velocity fields in the RPA are compared between the different methods at the same location during maximal forward flow (left) and deceleration flow (right). The **reference** case (top) presents no instability because the flow is smoother at its distal outlets, which is typical of bifurcations quite downstream of complex flow [39]. At maximal forward flow, it shows complex flow in the RPA. This behavior is retrieved on the short model with the **3D-0D** coupling method but with inwards velocity vectors. However, the computation is close to divergence. The **3D-0D-Stab** coupling method efficiently kills the reverse velocity vectors at the coupling surface so that a similar forward flow motion to the **3D-0D** coupling method is retrieved without backflow. Note that the **3D-3D** coupling leads to a velocity profile closer to the reference case.

Regarding blood flow behavior during the decelerating phase (right column in Figure 8), there is reverse flow in the **reference** case and a large proportion of the forward flow is located at the bottom of the surface area. With the **3D-0D** coupling method at outlet surfaces of the cut model, the computation is diverging, but the **3D-0D-Stab** coupling method leads to a blood flow behavior where velocity vectors are underestimated at the center and top of the coupling surface area. In

Figure 8: Velocity fields in RPA at peak inlet flow (left, $t=0.0936\text{s}$, $Q_{max} = 11.2\text{ cm}^3/\text{s}$) and during decelerating flow (right, $t=0.156\text{s}$) comparing the **reference**, **3D-0D**, **3D-0D-Stab**, **3D-3D** and **3D-3D-0D** coupling methods from top to bottom. The two times are shown as dots on the inflow Figure 7. Color encodes velocity magnitude from 0 (blue) to 90 cm/s (red).

the **3D-3D** coupling approach, flow motion is more homogeneous in terms of size and direction of the velocity vectors. The **3D-3D-0D** coupling method leads during maximal forward flow to a velocity field close to the coupling of reduced model with the **3D-0D-Stab** method. During deceleration the majority of flow is located at the bottom of the coupling surface and backflow is authorized in the upper part. The obtained flow behavior is thus close to the **reference** case. The velocity field for the **3D-0D-Ptot** coupling method behaves as in the previous patient-specific case of adult pulmonary arteries. However, the computation is diverging.

In the figures above, the RPA side is presented. In fact, the LPA is turning in the downstream 3D domain of the **reference** case in such a way that hemodynamics are even more different between the reference and the cut models than for the RPA. Next, the resulting flow rates are compared at coupling surfaces (Figure 9 shows as an example the RPA), between the **3D-0D** , **3D-0D-Stab** , **3D-3D** and **3D-3D-0D** coupling models. In all cases, most of the flow goes to the RPA, following a dynamics close to that of the inlet flow, with a peak in systole followed by a rapid decay. The flow rates oscillate in time in diastole due to the complex flow structures created by the interaction of the impinging inflow and the patient-specific geometry. However, for the **3D-0D** case the flow rates largely oscillate before the simulation diverges. In terms of magnitude, the coupling method that is closer to the **reference** case is the **3D-0D-Stab** method, on both sides. The **3D-3D** coupling approach is leading to a satisfying blood flow behavior but changes the distribution of flow between the left and right-hand sides for this choice of parameters: it slightly overestimates flow in the RPA and thus underestimates flow in the LPA. However, the hybrid coupling method **3D-3D-0D** is close to the **reference** case. The diverging **3D-0D-Ptot** results are not represented because the simulation

410 diverged early on ($t=0.0936s$).

Figure 9: Flow rate (left) and pressure (right) over two cardiac cycles in the RPA for the different coupling methods.

411 Lastly, Figure 9 shows the corresponding pressure waveforms. The time dy-
 412 namics are similar for all cases and on both sides, except for the **3D-0D** case which
 413 diverges in the first cardiac cycle. After the transitory first cycle, the second cycle is
 414 closer to a periodic solution with a sharp rise in systole, followed by a smooth dias-
 415 tole decay. The closest results to the **reference** case is the **3D-0D-Stab** method for
 416 both sides. The **3D-3D** approach underestimates pressure for both sides. However
 417 the hybrid **3D-3D-0D** coupling approach more closely reproduces the **reference**
 418 results.

419
 420 To summarize this case, both **3D-0D** and **3D-0D-Ptot** couplings lead to divergence
 421 of the simulation, although there is negative flow rate neither at the inlet nor at the
 422 outlets. This is highlighting the need for robust numerical methods in the pres-
 423 ence of complex flow, such as the **3D-0D-Stab** and **3D-3D** or **3D-3D-0D** coupling
 424 methods. The three presented similarities and differences with the **reference** case,
 425 which is the ground truth, **3D-3D-0D** being the best compromise in this example.

427 3.3. Adult patient-specific aorta: complex flow generated during deceleration

428 This last patient-specific case is an abdominal adult aorta. Figure 10 consists of
 429 the inlet flow rate over time and the three tested geometrical models: the complete
 430 3D model containing 608K tetrahedra and 9 outlet surfaces, the short model con-
 431 taining 473K tetrahedra and 6 outlet surfaces where the abdominal aorta was cut
 432 to remove the iliac branches, and the same cut model but with an artificial 3D part
 433 at its descending aorta outlet, containing 499K tetrahedra. Velocity is prescribed
 434 at the inlet of the model, as a plug profile following the flow tracing of Figure 10.
 435 As is typical in the supra celiac descending aorta, this flow rate does not contain
 436 reverse flow over the entire cardiac cycle. The maximal flow is $Q_{\max} = 177 \text{ cm}^3/\text{s}$

437 and the minimal flow is $Q_{\min} = 7 \text{ cm}^3/\text{s}$. Deceleration is large enough to gener-
 438 ate complex flow behavior in all the geometrical models regardless of the outlets
 439 coupling methodology at hand. The complete model is the **reference** where three
 440 dimensional Navier-Stokes equations are coupled to reduced models at every outlet
 441 with the **3D-0D** coupling method.

442

Figure 10: Top: imposed inflow (cm^3/s) shown over two cycles. Below, from left to right: the complete 3D model, the cut 3D model and the cut 3D model with its artificial 3D part tagged “cork”. The outlets are all labeled for future reference.

443 Table 4 contains the values of the proximal and distal resistances, and capacitances

444 for each of the nine outlets of the complete geometrical model. These values have
445 been set to match clinical measurements [41].

	1	2	3	4	7
R_p	$9.63 \cdot 10^2$	$2.96 \cdot 10^2$	$5.98 \cdot 10^2$	$3.57 \cdot 10^2$	$1.46 \cdot 10^3$
C	$6.21 \cdot 10^{-5}$	$7.67 \cdot 10^{-4}$	$3.80 \cdot 10^{-6}$	$1.40 \cdot 10^{-6}$	$3.03 \cdot 10^{-5}$
R_d	$3.36 \cdot 10^4$	$1.03 \cdot 10^4$	$1.48 \cdot 10^4$	$2.51 \cdot 10^4$	$1.14 \cdot 10^5$

	8	9	10	11
R_p	$1.08 \cdot 10^3$	$4.86 \cdot 10^2$	$2.70 \cdot 10^1$	$1.59 \cdot 10^3$
C	$6.91 \cdot 10^{-5}$	$3.70 \cdot 10^{-6}$	$2.13 \cdot 10^{-5}$	$3.09 \cdot 10^{-5}$
R_d	$4.35 \cdot 10^4$	$1.49 \cdot 10^4$	$1.55 \cdot 10^4$	$1.15 \cdot 10^5$

Table 4: Reduced model parameters for each outlet of the **reference** model, as labeled in the full model of Figure 10. R_p and R_d in $\text{g cm}^{-4} \text{s}^{-1}$, and C in $\text{g}^{-1} \text{cm}^4 \text{s}^2$.

446 Table 5 contains values of proximal and distal resistances, and capacitances
447 for each of the six outlets of the cut geometrical model. These reduced model
448 parameters for the cut abdominal outlet surface (cut2) were not generated from the
449 ones of the four outlet surfaces of the reference model (labeled 1,7, 8 and 11) as
450 was done in the previous test case, as this was leading to too inaccurate results.
451 Instead, the three Windkessel model parameters of this cut outlet were identified
452 by a Kalman filtering approach based on the flow and pressure tracings from the
453 reference simulation [34, 35].

	cut1	cut2	cut3	cut4	cut6	cut7
R_p	$4.86 \cdot 10^2$	$8.21 \cdot 10^2$	$3.57 \cdot 10^2$	$2.96 \cdot 10^2$	$2.70 \cdot 10^1$	$5.98 \cdot 10^2$
C	$3.70 \cdot 10^{-6}$	$2.05 \cdot 10^{-4}$	$1.40 \cdot 10^{-6}$	$7.67 \cdot 10^{-4}$	$2.13 \cdot 10^{-5}$	$3.80 \cdot 10^{-4}$
R_d	$1.49 \cdot 10^4$	$2.13 \cdot 10^4$	$2.51 \cdot 10^4$	$1.03 \cdot 10^4$	$1.55 \cdot 10^4$	$1.48 \cdot 10^4$

Table 5: Reduced model parameters for each of the six outlet of the cut model (for the **3D-0D** and **3D-0D-Stab** coupling methods), as labeled in Figure 10. R_p and R_d in $\text{g cm}^{-4} \text{s}^{-1}$, and C in $\text{g}^{-1} \text{cm}^4 \text{s}^2$.

454 Table 6 contains values of proximal and distal resistances, and capacitances for
455 each of the five outlets of the original part and coefficient α , β and γ for the **3D-3D**
456 model in the artificial part. The latter were chosen given that the added volumes

are such that V , S and L are respectively 1.8 cm^3 , 1.8 cm^2 , and 1 cm . For the **3D-3D-0D** model, the values are the same, except for the artificial part for which changes are described at the beginning of the results section.

Table 6: Reduced model parameters for each outlet of the **3D-3D** coupling model, as labeled in the cut model with “cork” in Figure 10. R_p and R_d in $\text{g cm}^{-4} \text{ s}^{-1}$, and C in $\text{g}^{-1} \text{ cm}^4 \text{ s}^2$, α in $\text{g}^{-1} \text{ cm s}^2$, β in $\text{g}^{-1} \text{ cm s}$, and γ in $\text{g cm}^{-3} \text{ s}^{-1}$.

Hemodynamics are compared through the cut abdominal aortic surface of the reference simulation with the abdominal aortic outlet of the other models. On the left column of Figure 11, i.e. during forward flow, the velocity field behavior is closer to the **reference** for the **3D-0D** coupling and thus also for **3D-0D-Stab** method since the vectors are all pointing outwards. The **3D-3D** approach leads to a flatter velocity profile. **3D-3D-0D** is in between these two methods. However, during reverse flow, the **reference** case concentrates the higher velocity magnitudes on the exterior part of the surface area. The **3D-0D** coupling method results in high central velocity vectors, eventually leading to divergence of the simulation. This time, the **3D-0D-Stab** and **3D-3D-0D** coupling exhibit some backflow but with a homogeneous distribution of velocity vectors on the surface area. The **3D-3D** model is similar, but with velocity magnitude closer to the average **reference** case. Figure 12 shows the **Ptot** coupling method results, with spurious radial velocity vectors, exhibiting here particularly the well-known effect of the total pressure coupling [22]. In this case the simulation actually diverges.

476

Figure 11: Velocity fields at two different times, $t=0.21s$ (maximal forward inlet flow, left) and $t=0.46s$ (maximal reverse flow at outlet, right) for from top to bottom: **reference**, **3D-0D**, **3D-0D-Stab**, **3D-3D** and **3D-3D-0D** coupling models. Color encodes for velocity magnitude from 0 (blue) to 50 cm/s (red).

Figure 12: Velocity fields during maximal forward flow with the **3D-0D-Ptot** coupling model.

Next, in Figure 13, the resulting time-varying flow rates are compared at the same surface, between the **3D-0D** , **3D-0D-Stab** , **3D-3D** and **3D-3D-0D** coupling models. All cases follow a dynamics with a peak in systole followed by a rapid deceleration with significant flow reversal and then forward flow again in the last part of diastole. The curves are neither completely synchronized in time nor matching completely in amplitudes. This time, for the **3D-0D** case the flow rate does not largely oscillate before the simulation diverges. Moreover the **3D-0D-Stab** coupling method is disturbing the blood flow behavior, with a flow rate amplitude lower than the reference one, where maximum flow is lower and minimum flow is higher than reference flow rate. The **3D-3D** follows closely. The coupling method that reproduces as best as possible the flow tracing from the reference case is the **3D-3D-0D** coupling method even if the minimum flow is overestimated.

In Figure 14, the corresponding pressure curves are compared: although they all follow the same typical pressure dynamics of a peak in systole followed by a smooth decay in diastole, all coupling methods overestimate the reference pressure. They are all shifted in time differently than for the flow rates. The **3D-0D** case overestimates pressure the least, but it diverges in diastole. For this test case, the **3D-0D-Stab** method is the furthest from the reference case whereas the **3D-3D-0D** coupling model is the closest. The **3D-3D** coupling approach is in between in terms of magnitude, but with an additional time shift.

Figure 13: Flow rates over two cardiac cycles at the infrarenal (cut2) coupling interface, with the different coupling methods.

497

Figure 14: Surface-averaged pressure over two cardiac cycles at the infrarenal (cut2) coupling interface with the different coupling methods.

498 In summary for this case, one can observe that both **3D-0D** and **3D-0D-Ptot** cou-
499 plings lead to divergence of the simulation, due to the negative flow rate at the
500 outlet, although the flow is entering at the inlet. Such a flow rate difference is
501 typical of these abdominal aorta locations [41]. In all the converging cases during
502 back flow, the velocity vectors are all aligned in the same inward direction. The
503 **3D-0D-Stab** , **3D-3D** and **3D-3D-0D** coupling methods presented similarities and
504 differences with the **reference** case, which is the ground truth, **3D-3D-0D** being
505 again the best compromise in this example.

506

507 **4. Discussion and Conclusion**

508 *4.1. Divergence behavior*

509 Different existing methods have been implemented and compared to couple three-
510 dimensional finite element Navier-Stokes simulations to lumped parameter models,
511 and in particular to the three-element Windkessel model. Differences in numerical
512 implementations that might also affect numerical stability (e.g [31] and references
513 therein) are not discussed here, but rather coupling approaches at the continuous
514 level. The first (standard) idea has been to impose weakly that at the coupling inter-
515 face the normal component of the stress tensor is equal to a surface-homogeneous
516 pressure computed from the reduced model. Such a coupling was shown above to
517 lead to an (uncontrolled) convective boundary energy term, potentially destabiliz-
518 ing with flow reversal at the interface. In presence of complex flow at that location,
519 simulations are diverging in the patient-specific examples presented above. This
520 behavior is consistent with other examples from the literature [1, 40]. Note that for
521 the two last patient-specific cases, although the same **3D-0D** coupling was imposed
522 in the full 3D-models, the simulations did not diverge: as the geometry branches
523 off, flow gets more streamlined as observed in [39, 40]. To get rid of this poten-

524 tially destabilizing boundary convective term, the **3D-0D-Ptot** coupling method
525 was also implemented. This coupling approach was considered for example in
526 [5, 22]. Similarly to what [22] observed already for stationary flow in a pipe, ab-
527 normally large radial components of the velocity vectors at the coupling surface
528 were observed during forward flow. Likely because of higher Reynolds numbers
529 and more complex flow in these patient-specific cases, spurious peripheral inward
530 and out of plane velocity vectors were seen, even in case of forward flow. This
531 generated abnormally large in-plane pressure gradient and eventually lead to diver-
532 gence of the simulations when forward flow became higher.

533

534 *4.2. About the convective stabilisation*

535 These two methods highlighted the sensitivity of the simulation stability to the
536 choice of coupling method. It is not a priori possible to predict which simulation
537 will be stable throughout or diverge. Since the first coupling only diverges typi-
538 cally with some inward and non-zero tangential velocity vector or complete back
539 flow at the coupling interface, natural ideas are to enforce the tangential compo-
540 nent to be zero or to even constrain the whole velocity profile. As these have been
541 shown to be non-ideal [29], here the convective **3D-0D-Stab** method was retained.
542 Recall that it only acts when velocity vectors point inwards at the coupling inter-
543 face. It was introduced in [4] for cardiovascular applications with an energetically
544 over-stabilizing effect as discussed above, and successfully tested with a smaller
545 energy-dissipative coefficient (a value of θ of 0.5 or less was found enough to en-
546 sure stability) in [29, 31, 32] in cardiovascular and respiratory contexts. In these
547 papers, without this stabilization the simulations would have diverged. Here the
548 version that exactly annihilates the energetically destabilizing convective term was
549 implemented. It leads in fact to a similar stabilizing behavior. The present re-

sults highlight the robustness of this method under different conditions of complex and back flows. However such a coupling involves enforcing an ad-hoc inhomogeneous normal stress over the interface area and in practice generally induces an over-killing of the inward velocity vectors. Besides, as noted by [36], this leads to a weak formulation that is not consistent with the original strong boundary condition of the reduced model coupling. A consistent formulation (with a value of θ of one) has been proposed by [20] in respiratory mechanics (see this reference for earlier references about imposition of total momentum flux) but it requires to also prescribe the convective term and thus to know the velocity vectors at the coupling boundary or to make some further assumption on the velocity profile at the boundary [20, 23]. The convective stabilization with $\theta = 1$ resulted in single tube cases in a flatter velocity profile than in their total momentum flux case. It is interesting to note that in respiratory applications for which the back flow is very significant (whole expiration phase), the necessity to stabilize the convective term one way or another was found crucial [23, 26, 32].

565

4.3. Discussion on the modified Navier-Stokes method, its advantages and limits

One of our main aims was thus to develop a new three-dimensional finite element coupling method where reduced model parameters were three-dimensionally distributed in a modified Navier-Stokes equation into a small outer portion. The goal was to obtain a blood flow behavior as close as possible to a **3D-0D** coupling into an extended geometrical model with more branches. From a theoretical point of view, this approach has the advantage that it does not necessitate a coupling condition at the interface: it thus does not enforce the normal component of the stress to be homogeneous as in the **3D-0D** method or inhomogeneous in an ad-hoc way as in the **3D-0D-Stab** method. Another advantage is that it generates an energy balance

576 that is similar to the **3D-0D** method, but, if the distal boundary of the modified part
 577 is set to zero velocity (as was done in the **3D-3D** simulations), it does not include
 578 the potentially destabilizing convective boundary term. If this distal velocity is not
 579 zero (as was the case in the **3D-3D-0D** simulations), the velocity field is damped
 580 and smoothed by the modified portion before it reaches the boundary, so it does
 581 not develop instabilities in practice.

582 Numerically, as a general trend, the results suggest that the **3D-0D-Stab** coupling
 583 method is more accurately reproducing forward flow whereas during deceleration
 584 or reverse flow it is less invasive to use the three-dimensional coupling **3D-3D** ap-
 585 proach than the robust **3D-0D-Stab** model. An excellent compromise was reached
 586 by the **3D-3D-0D** method, a hybrid method which regularizes the flow in an ar-
 587 tificial portion, with a small dissipative term, representing a small fraction of the
 588 proximal resistance. It effectively stabilized the simulations, without significantly
 589 affecting forward flow but allowing more freely inward velocity vectors than the
 590 **3D-0D-Stab** method. Regarding pressure and flow tracings at the coupling inter-
 591 faces of the three patient-specific cases, all coupling methods could reproduce the
 592 general temporal dynamics, unless they diverged. However, quantitative pressure
 593 and flow differences could be observed. In fact, in biomedical applications, the ex-
 594 isting coupling methods and the ones developed in this article all involve tuning of
 595 the distal parameters in order to be as coherent as possible to clinical hemodynam-
 596 ics measurements [43]. Such tuning was not the focus of this work, and is matter of
 597 intense recent research (e.g [1, 7, 13, 24, 34, 35, 38, 39]). Here, when the reference
 598 model (extended model with Windkessel reduced models at its ends) was available,
 599 it was quite simple to deduce or automatically tune the corresponding Windkessel
 600 model at the coupling interface of the cut model. This made sure that the **3D-0D**
 601 and **3D-0D-Stab** results were close to the **reference** case. However, such equiv-
 602 alence or tuning was less obvious to do for the new **3D-3D** parameters (α , β and

603 γ): a better match of the pressure and flow waveforms could be achieved by man-
604 ually tuning these parameters, but we thought it would make more sense to present
605 the results with the most straightforward parameterization. Actually in general the
606 reference model would not be available (otherwise it would be used without cut-
607 ting) and the modified Navier-Stokes parameters (in its original or hybrid version)
608 would be tuned in order to match clinical hemodynamics measurements instead of
609 matching reduced model parameters R_p , C and R_d . This approach is not developed
610 at this time and could be part of future work. Another important question that was
611 not addressed in detail here is the length of the artificial domain. Size should not of
612 course be too large to avoid unnecessary additional computational cost. If it is too
613 small, pressure and velocity change too abruptly (**3D-3D**) or the velocity field is
614 not regularized enough before hitting the outlet (**3D-3D-0D**). We have not carried
615 out an extensive sensitivity analysis on the subject, but we noticed that multiplying
616 the cork volume of the presented results by a factor two did not affect the numerical
617 stability of the solution.

618

619 *4.4. Comparison between cut and reference models*

620 Interestingly, several methods lead to more similar results between each other than
621 compared to the non-cut reference model. This is particularly true when the down-
622 stream part is geometrically different than the upstream, as was the case of the LPA
623 in the child pulmonary example. The distribution of flow rates among the different
624 downstream vessels can also affect the flow in the non-cut upstream region. This
625 highlights the importance of including enough downstream geometry to not affect
626 the area of interest in the three-dimensional part in biomedical applications [1, 39].

627

628 4.5. Possible extension of the work

629 Finally, this **3D-3D** method could be extended to a more extensive lumped pa-
630 rameter model through the β term. The latter could include a distal pressure, rep-
631 resenting the link with the rest of the reduced model. Furthermore, it would be
632 interesting to implement a space-varying γ parameter. This dissipative term in the
633 Navier-Stokes equation is known to regularize the velocity profile to a plug-like
634 profile (like at the interface with a porous medium), which helps here to stabilize
635 the simulation but is also responsible for a significant impact on the velocity field
636 at the interface. The coupling approach would be less invasive in particular dur-
637 ing forward flow if this parameter was changing more smoothly. This is probably
638 why the **3D-3D-0D** was found to be the best compromise between robustness and
639 non-invasiveness.
